2003 Sexually Transmitted Diseases In Illinois Introduction

The Illinois Department of Public Health (IDPH) Sexually Transmitted Disease (STD) Program is pleased to present the *2003 Illinois Sexually Transmitted Diseases Summary*. This summary provides statistics and trends of reported sexually transmitted diseases (STDs) in Illinois for 1993-2003 and consists of five sections: Illinois 2003 epidemiologic summary; Illinois statewide statistics tables; and chlamydia, gonorrhea and syphilis cases, rates and county demographics statistics tables. Data from IDPH laboratories on viral STDs (herpes and hepatitis C) from testing performed at STD clinics and selected outreach sites are included in the 2003 Epidemiologic Summary section.

The Illinois Control of Sexually Transmitted Diseases Code [77 Illinois Administrative Code 693] requires physicians, laboratories and blood banks to report within seven days to the local health authority (i.e., county/city health department or IDPH for jurisdictions where there is no health department) all diagnosed cases and positive laboratory findings of reportable STDs (syphilis, gonorrhea, chlamydia and chancroid). Reports of diagnosed cases of reportable STDs are submitted by health care providers on morbidity reporting forms, "Confidential Morbidity Report of Sexually Transmitted Diseases," furnished by IDPH. These morbidity reports are submitted to the local health authority and then forwarded to IDPH. Morbidity data are tabulated by program staff from these reports.

STD case rates for 1993-1999 were calculated using population figures from 1990 U.S. census data, and 2000-2003 case rates were calculated using population data from the 2000 U.S. census. Rates reflect the number of cases per 100,000 population. Congenital syphilis rates represent the number of infants with congenital syphilis per 100,000 live births in each of the respective years. The source for all charts and tables included in this summary is the IDPH STD Program. This document, along with more recent data on STD trends in Illinois, is also available by Internet via the IDPH home page at <www.idph.state.il.us>.

Disease incidence in the city of Chicago and surrounding suburbs of Cook County has a major effect on STD morbidity trends in Illinois. According to the 2000 U.S. census, Cook County accounts for 43 percent of the total Illinois population. During 2003, Chicago and surrounding Cook County suburbs accounted for 64 percent of total reported STDs in Illinois. Because of the significant incidence of STDs in Cook County, data are delineated throughout this document for Illinois, Chicago, and Illinois excluding Chicago.

This report was prepared by IDPH STD Program staff.

Charlie Rabins, M.P.H., *Chief, STD Program*

Alice Studzinski, *Surveillance and Evaluation Coordinator, STD Program* [Editor]

Mark S. Dworkin, M.D., M.P.H.T.M., *State Epidemiologist*

The STD Section acknowledges and appreciates the efforts of local health departments, hospitals, physicians and laboratories to report STDs and of IDPH support staff for processing and tabulating the reports.

Questions concerning STD reporting requirements in Illinois or data contained in this document should be directed to your local health department or to the IDPH STD Section at 217-782-2747, TTY (for hearing impaired use only) 800-547-0466.

Section 1.

Sexually Transmitted Diseases
Illinois Epidemiologic Summary, 2003

**Chlamydia, Gonorrhea, Syphilis,
Herpes and Hepatitis**

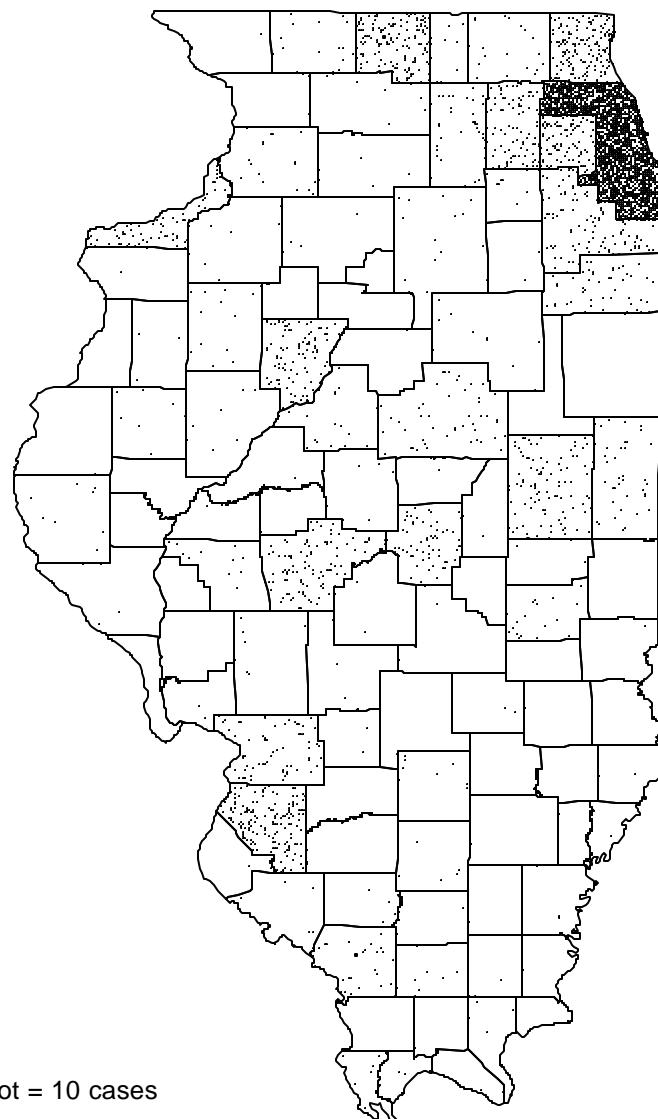

The following section presents an epidemiologic summary and demographic profile of reported sexually transmitted diseases in Illinois during 2003, the results of herpes testing and hepatitis vaccination activities at Illinois STD clinics, syphilis behavioral risk assessment outcomes, and behavioral risk assessment data for STD clinic clients in Illinois outside of Chicago.

2003

**Figure 1. Illinois Reported Chlamydia Cases
Distribution by County, 2003**

2003

2003 Chlamydia Summary

Chlamydia trachomatis infection is a significant cause of genitourinary complications, especially in women. Early symptoms are often mild, and asymptomatic infection is common in both men and women. Untreated chlamydia in women may lead to pelvic inflammatory disease (PID) with severe fallopian tube inflammation and damage. Chlamydia is a major cause of long-term sequelae such as tubal infertility and ectopic pregnancy and can cause premature rupture of membranes in pregnant women. Newborns exposed during birth may develop ophthalmia neonatorum or pneumonia.

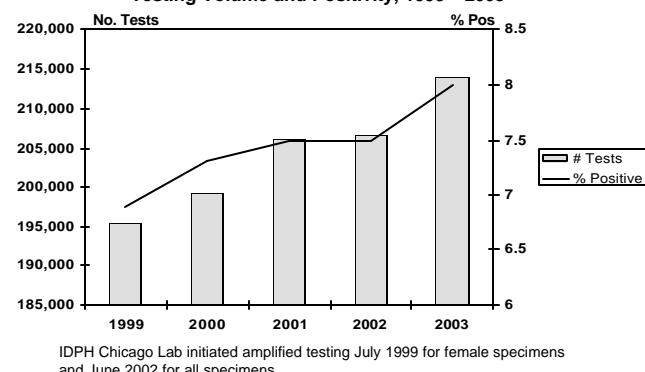

In Illinois, a case of chlamydia infection is defined as the isolation of *C. trachomatis* by culture, or demonstration of *C. trachomatis* in a clinical specimen by detection of antigen or nucleic acid.

Chlamydia first became reportable in Illinois in July 1987. From 1993 through 2003, the number of reported cases increased 96 percent from 24,603 to 48,294. Reasons for the increase include improved surveillance procedures, increased testing and the use of more sensitive diagnostic tests. Adolescents ages 15-19 years accounted for 33 percent (16,071) of chlamydia cases reported during 2003 and had an incidence rate of 1,797.6 compared to 388.9 for the total Illinois population. Among age groups, the highest case rate, 2,112.7, was among young adults ages 20-24 years. The average age, where age was known, of reported chlamydia cases during 2003 was 23 years - 25 years for males and 22 years for females.

Chlamydia screening programs target women because they are frequently asymptomatic and the complications of untreated infection are severe. Because screening programs test clients regardless of symptoms, they help to establish the prevalence of infection in population groups. During recent years, as testing has become more widely available and affordable, screening programs have been expanded in STD clinics, school-based health centers, adult and juvenile correctional centers, and women's health programs such as family planning and prenatal clinics. Chlamydia screening sites conducted more than 213,000 tests during 2003 (49,486 in men and 164,220 in women); the positivity rate was 8.0 percent - 6.9 percent for females and 12.0 percent for males. Specimens collected from clients 15-24 years of age accounted for 57 percent of all tests and 74 percent of all positive tests; the positivity rate was 5.9 percent for this age group. Adolescent and young adult females are at particular risk for chlamydia infection. The positivity rate in 2003 for chlamydia screening site specimens from females ages 15-24 years was 16.1 percent from adult and juvenile correctional centers, 15.6 percent from STD clinics, and 13.7 percent from school-based health clinics.

Positivity rates for chlamydia screening site specimens increased beginning in 2003 because of the implementation in June 2002 of a nucleic acid amplified test (NAAT) at IDPH laboratories (Figure 2).

Figure 2. Illinois Chlamydia Testing and Screening Sites
Testing Volume and Positivity, 1999 - 2003

2003 Chlamydia Epidemiologic Profile

Five-Year Trends

Reported cases of chlamydia increased 33 percent (36,409 to 48,294) from 1999 to 2003. There was a 36 percent (18,284 to 24,828) increase in the state excluding Chicago, and a 29 percent (18,125 to 23,466) increase in Chicago (Figure 3).

Where

During 2003, of the 48,294 reported cases of chlamydia, 23,466 (49%) were from Chicago and 24,828 (51%) from Illinois excluding Chicago. The case rate per 100,000 population was 388.9 for Illinois, 810.3 for Chicago, and 260.7 for Illinois excluding Chicago.

Cases were reported from all of the 102 counties in Illinois. The greatest number of cases was reported from Cook County, 29,715 (62%). The highest incidence rates per 100,000 population were reported from the following five counties: Alexander, 750.8 (72 cases); Pope, 725.1 (32 cases); St. Clair, 668.9 (1,713 cases); Champaign, 588.9 (1,058 cases); and Peoria, 567.7 (1,045 cases) (Figure 4).

Who

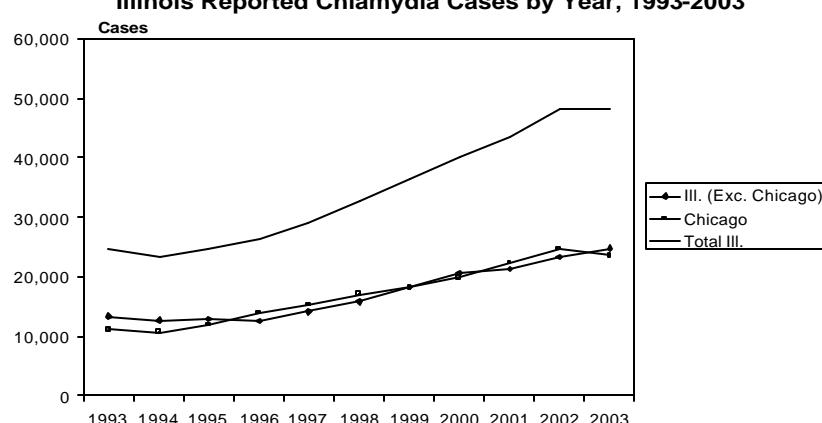

The racial/ethnic distribution of cases during 2003 was 60 percent non-Hispanic African American (24,433), 18 percent non-Hispanic white (8,555), less than 1 percent non-Hispanic Asian/Pacific Islander and Native American (265), 9 percent Hispanic (4,184), and 23 percent other or unknown race/ethnicity (10,857) (Figure 5). The highest case rate was among African Americans, 1,301.8.

Adolescents and young adults ages 15-24 years accounted for 71 percent (34,047) of reported cases during 2003 where age was known (Figure 6). Age was missing from 45 records.

The ratio of identified and reported female cases to males during 2003 was 3.0:1.0. This ratio likely overestimates the true ratio because screening programs target females. During recent years, testing in males has increased. Cases among males increased 57 percent (7,642 to 12,009) from 1999 to 2003 (Figure 7).

Hospitals and private physician offices reported the greatest percentage of chlamydia cases during 2003, 57 percent (27,698). Other providers included STD clinics, 16 percent (7,649); family planning clinics, 12 percent (5,786); and correctional facilities, 5 percent (2,437).

2003

**Figure 8. Illinois Reported Gonorrhea Cases
Distribution by County, 2003**

2003

2003 Gonorrhea Summary

Gonorrhea is a bacterial infection caused by *Neisseria gonorrhoeae*. Uncomplicated urogenital infection may progress, without treatment, to complications such as pelvic inflammatory disease (PID), infertility and disseminated infection. Resultant scarring of fallopian tubes can cause ectopic pregnancy. Women are more likely than men to suffer complications from gonorrhea infection because early symptoms are often not present or so mild as to not be recognized by the female. Infants born to infected mothers may develop gonococcal ophthalmia, which is potentially blinding, or sepsis, arthritis or meningitis.

In Illinois, a case of gonorrhea is defined for surveillance purposes as isolation of typical gram-negative, oxidase positive diplococci (presumptive *N. gonorrhoeae*) from a clinical specimen; demonstration of *N. gonorrhoeae* in a clinical specimen by detection of antigen or nucleic acid; or observation of Gram-negative intracellular diplococci in a male urethral or female endocervical smear.

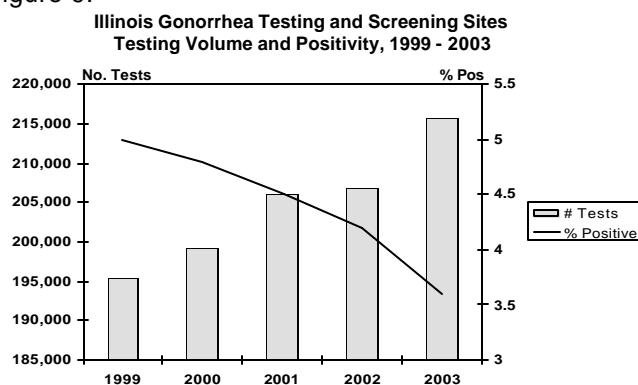

From 1993 through 2003, reported cases of gonorrhea decreased by 18 percent from 26,593 to 21,817. Reported cases decreased by 9 percent (24,026 to 21,817) during 2003 compared to 2002. This decrease was partially a reporting artifact. In May 2003, the Cook County Jail in Chicago discontinued gonorrhea screening of inmates due to financial constraints, resulting in a 57 percent (1,682 to 731) decrease in reported cases. Despite the small statewide decrease, there were several local outbreaks. Twelve local health departments located throughout Illinois that reported at least 10 cases during 2003 in their jurisdictions recorded increases of more than 50 percent compared to 2002.

Teens and young adults are disproportionately affected by gonorrhea in Illinois. Infected persons ages 15-24 years accounted for 61 percent (13,252 of 21,817) of reported cases during 2003. The case rate for adolescents ages 15-19 years was 680.8 compared to 175.7 for the total population. The highest case rate, 842.2, was among young adults ages 20-24 years. The average age of reported gonorrhea cases during 2003, where age was known, was 25 years - 27 years for males and 23 years for females.

Several currently available laboratory tests have the capability to identify chlamydia and gonorrhea from the same specimen, thus eliminating the need for collecting two specimens. Implementation and expansion of chlamydia screening programs therefore has resulted in the additional benefit of increased testing for gonorrhea. The gonorrhea positivity rate decreased from 5.0 percent to 3.6 percent between 1999 and 2003 because of more screening and a general decline in gonorrhea incidence (Figure 9). Illinois gonorrhea testing and screening sites processed more than 213,000 gonorrhea tests during 2003 (49,510 from males and 164,358 from females). The positivity rate in 2003 was 3.7 percent - 2.1 percent for females and 8.9 percent for males.

Specimens collected from clients ages 15-24 years accounted for 57 percent of all specimens and 63 percent of all positive tests; the positivity rate was 4.3 percent in this age group. The highest positivity rates identified in clients ages 15-24 years were reported from STD clinics (10.8%), hospitals (8.7%), and correctional facilities (4.3%).

Figure 9.

2003 Gonorrhea Epidemiologic Profile

Five-Year Trends

Reported cases of gonorrhea decreased 10 percent (24,136 to 21,817) from 1999 to 2003. There was an 8 percent (8,967 to 9,696) increase in Illinois excluding Chicago and a 20 percent (15,169 to 12,121) decrease in Chicago (Figure 10).

Where

The total number of gonorrhea cases reported during 2003 was 21,817 - 12,121 (56%) in Chicago and 9,696 (44%) in Illinois excluding Chicago. The case rate per 100,000 population was 175.7 for Illinois, 418.5 for Chicago and 101.8 for Illinois excluding Chicago.

Cases were reported from 91 of the 102 counties. The greatest number of cases was reported from Cook County, 14,786 (68%). The highest incidence rates per 100,000 population were reported from the following five counties: Alexander, 365.0 (35 cases); Macon, 364.4 (418 cases); Sangamon, 357.2 (675 cases); St. Clair, 342.1 (876 cases); and Pulaski, 313.0 (23 cases) (Figure 11).

Who

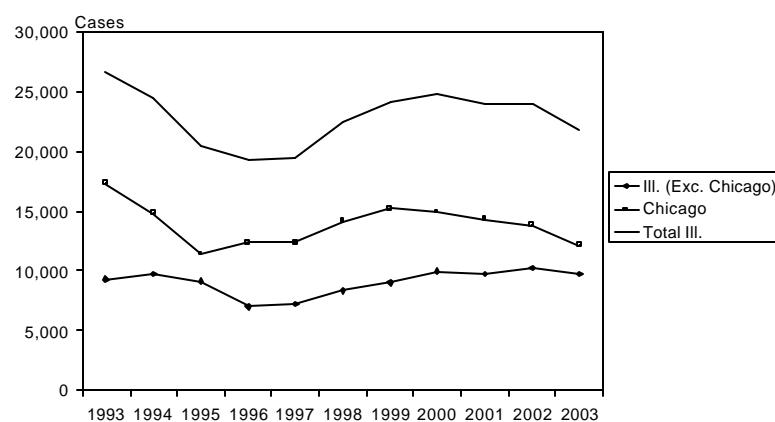

The racial/ethnic distribution of cases during 2003 was 66 percent non-Hispanic African American (14,426), 11 percent non-Hispanic white (2,357), less than 1 percent non-Hispanic Asian/Pacific Islander and Native American (77), 3 percent Hispanic (577), and 20 percent other or unknown race/ethnicity (4,380) (Figure 12). African Americans had the highest case rate among racial groups during 2003, but the case rate decreased 26 percent between 1999 and 2003, from 1,037.0 to 769.8.

Adolescents and young adults ages 15-24 years accounted for 61 percent (13,252) of reported gonorrhea cases where age was known during 2003 (Figure 13). Age was missing from only 18 records.

The ratio of identified and reported female cases to males during 2003 was 1.1:1.0, whereas in 1999 there were more males cases (12,559) reported than females (11,563), a female to male ratio of 0.9:1.0. Reported cases increased less than 1 percent (11,563 to 11,624) among females and decreased 19 percent (12,559 to 10,192) among males from 1999 to 2003 (Figure 14).

Hospitals and private physician offices reported 59 percent (12,800) of gonorrhea cases during 2003. Other reporting facilities included STD clinics, 25 percent (5,460); family planning clinics, 6 percent (1,303); and correctional facilities, 5 percent (1,024).

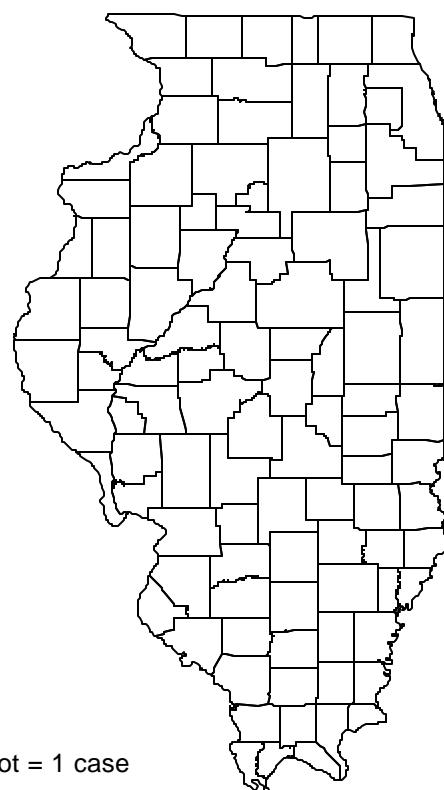

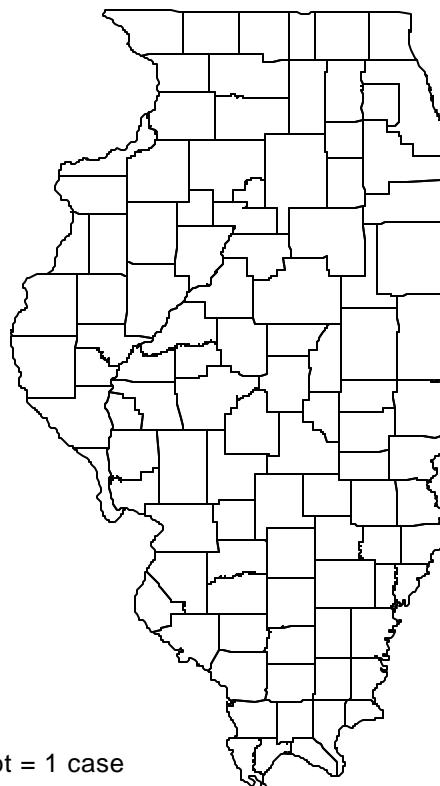

Figure 15. Illinois Reported Primary and Secondary Syphilis Cases Distribution by County, 2003

Figure 16. Illinois Reported Congenital Syphilis Cases Distribution by County, 2003

2003

2003 Syphilis Summary

Syphilis is a systemic disease caused by the spirochete *Treponema pallidum*. The infection is diagnosed through microscopic examination of lesion exudates and through serologic testing. *Early syphilis* refers to syphilis of less than one year duration. Untreated, it progresses through three stages - *primary* and *secondary*, which are characterized by infectious lesions, rashes and other systemic manifestations, and *early latent*, with no signs or symptoms present at the time of diagnosis. Public health disease intervention efforts emphasize control of early syphilis because persons with these stages of syphilis are most likely to have been infectious within the past year. Emphasis on data in this document is on primary and secondary syphilis because it is the best indicator of recent infection.

The number of early syphilis cases in Illinois is small in comparison to gonorrhea and chlamydia. However, significant public health resources must be devoted to control of syphilis for several reasons. Untreated syphilis can result in complications that include neurological or cardiovascular damage. Syphilis also can be transmitted to a fetus from an infected woman during pregnancy. This condition, called *congenital syphilis*, can cause stillbirth and severe illness or death to the infected newborn. The open lesions and resultant enhanced immune response during primary and secondary syphilis can increase the risk of HIV transmission and acquisition for infected persons by three- to five-fold. HIV and syphilis co-infection can result in complications for both diseases. HIV infection can occasionally cause unusual serologic syphilis test results and cause the clinical course of syphilis infection to be accelerated and more aggressive. Without treatment, approximately 10 percent of persons infected with syphilis will develop neurosyphilis, but in those persons co-infected with HIV, 25 percent may develop this complication. Syphilis infection can destabilize the course of HIV infection and necessitate adjustments in HIV treatment.

Primary and Secondary Syphilis

Reported primary and secondary syphilis cases decreased 75 percent between 1993, when 1,489 cases were reported, and 2003 when there were only 374 reported cases. Reported cases decreased by 22 percent from 2002 to 2003 (479 to 374), indicating that an outbreak among men who have sex with men (MSM) identified in 2002 is resolving. Five local health departments reported outbreaks of syphilis in their jurisdictions during 2003: Lake County, DuPage County, Oak Park, East Side Health District and Madison County.

During 2003, white males and African American females were disproportionately affected by syphilis. Although cases decreased 20 percent (200 to 160) among white males from 2002 to 2003, white males accounted for the greatest percentage by race of all reported cases in 2003 - 43 percent of all reported cases and 49 percent of male cases. African American females accounted for 85 percent of the 48 female cases reported in 2003. The highest primary and secondary syphilis case rate (9.2) was reported among African Americans.

Syphilis is identified more frequently among older age groups than gonorrhea and chlamydia. The average age of reported primary and secondary syphilis cases in 2003 was 36 years - 36 years for males and 33 years for females.

The majority of primary and secondary cases, 87 percent, reported during 2003 were males. Of these 326 males, 206 (63 percent) were MSM. Fifty-seven percent (117) of MSM were white. Of the 374 reported cases, 26 percent (99) were co-infected with HIV - 45 percent (92) of MSM, 5 percent (6) of non-MSM males, and 2 percent (1) of females.

During 2003, there were 24 cases of neurosyphilis reported. Of the 2003 cases, 21 (88 percent) were males; of these males, the majority (57 percent) were MSM. Ten (42 percent) of the persons reported with neurosyphilis were known to be co-infected with HIV.

2003

2003 Primary and Secondary Syphilis Epidemiologic Profile

Five-Year Trends

Reported primary and secondary syphilis decreased 11 percent (422 to 374) from 1999 to 2003. There was a 24 percent (140 to 107) decrease in Illinois excluding Chicago and a 5 percent (282 to 267) decrease in Chicago (Figure 17).

Where

The total number of primary and secondary syphilis cases reported during 2003 was 374: 267 (71%) in Chicago and 107 (29%) in Illinois excluding Chicago. The case rate per 100,000 population was 3.0 for Illinois, 9.2 for Chicago, and 1.1 for Illinois excluding Chicago.

Cases were reported from 16 of the 102 counties, a decrease from the 23 counties with reported cases in 2002. Most cases were reported from Cook County, 302 (81%). The highest incidence rates per 100,000 population were in the following five counties that reported at least three cases in 2003: Vermilion, 10.7; Cook, 5.6; Winnebago, 3.2; Madison, 3.1; and St. Clair, 2.7 (Figure 18).

Who

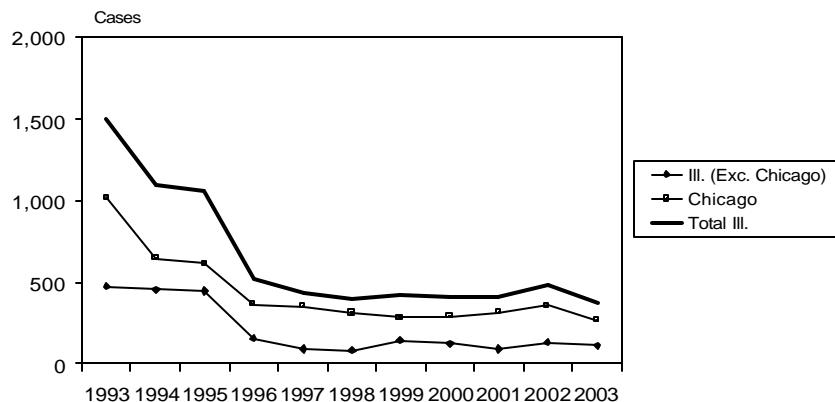

The racial/ethnic distribution of cases during 2003 was 45 percent non-Hispanic African American (171), 40 percent non-Hispanic white (148), 9 percent Hispanic (35), 1 percent non-Hispanic Asian/Pacific Islander (2) and 5 percent non-Hispanic other or unknown race (18) (Figure 19). African Americans had the highest case rate among racial groups during 2003, but the rate decreased 53 percent from 1999 (19.7) to 2003 (9.2). This is the lowest rate recorded in Illinois among African Americans in over 15 years.

Adults, ages 25-44 years, accounted for 73 percent (271) of primary and secondary syphilis cases reported during 2003 (Figure 20).

The number of reported cases decreased 73 percent (180 to 48) among females and increased 35 percent (242 to 326) among males from 1999 to 2003 (Figure 21). The ratio of reported male cases to females during 2003 was 6.8:1.0 compared to 1.3:1.0 in 1999 (Figure 22).

STD clinics reported only 45 percent (169) of primary and secondary syphilis cases during 2003. Other reporting facilities included private physicians, 32 percent (119); hospitals, 17 percent (65); correctional facilities, 2 percent (9); and other facilities, 2 percent (12).

2003

Congenital Syphilis

Congenital syphilis is a condition caused by infection *in utero* with *Treponema pallidum*. A wide spectrum of clinical signs exist and not all cases are clinically apparent at birth. The surveillance case definition is outlined in the MMWR edition May 2, 1997 / Vol. 46 / No. RR-10; 1-55. This is not a clinical definition but a sensitive (nonspecific) surveillance definition. As a result, the reported cases likely overestimate the actual number of cases, but such a surveillance system helps to ensure that infants with congenital syphilis will not be missed by the public health system. Therefore, cases of congenital syphilis represent a mix of suspect, probable and confirmed congenital syphilis.

Reported congenital syphilis cases decreased 90 percent (368 to 21) between 1993 and 2003. The 2003 rate was 11.6 cases per 100,000 live births (2002 live birth statistics), the lowest rate in more than 10 years. African Americans were disproportionately represented among reported congenital syphilis cases, accounting for 90 percent (19) of cases.

In 2003, only 38 percent (8 of 21) of mothers of congenital syphilis cases received prenatal care. Treatment of an infected woman during early pregnancy can prevent infection of the fetus or cure an already infected fetus to prevent further complications. Illinois law (410 ILCS 320/1) requires screening for syphilis at the first prenatal visit and again during the third trimester.

2003 Congenital Syphilis Epidemiologic Profile

Five-Year Trends

Reported congenital syphilis decreased 65 percent (60 to 21) from 1999 to 2003. There was a 42 percent (12 to 7) decrease in Illinois excluding Chicago and a 71 percent (48 to 14) decrease in Chicago (Figure 23).

Where

The total number of congenital syphilis cases reported during 2003 was 21: 14 (67%) in Chicago and 7 (33%) in Illinois excluding Chicago. The case rate per 100,000 live births was 11.4 for Illinois, 29.2 for Chicago and 5.1 for Illinois excluding Chicago.

Cases were reported from five of the 102 counties, compared to eight counties with reported cases in 2002. The number of reported cases and case rates, respectively, for these counties were as follows: Cook, 16 (19.6); Vermilion, 2 (182.1); St. Clair, 1 (27.6); Lake, 1 (9.7); and DuPage, 1 (7.8) (Figures 16 and 24).

Who

African Americans were disproportionately affected by congenital syphilis in 2003. The racial distribution of cases during 2003 was 90 percent African American (19), 5 percent white (1) and 5 percent other or unknown race (1) (Figure 25). There were no cases reported among Hispanics.

The ages of women who delivered an infant with congenital syphilis during 2003 ranged from 21 to 43 years, with the 20-29 year age group accounting for 62 percent (13) of cases (Figure 26). The average age of the mothers was 29 years.

2003 Genital Herpes Summary

Genital herpes is a contagious viral infection that affects an estimated 45 million Americans (more than one in five). The infection is caused by the herpes simplex virus (HSV). It is usually acquired through sexual contact with someone infected with genital herpes. There are two types of HSV: HSV-1 and HSV-2. HSV-1 usually causes sores on the lips known as fever blisters or cold sores, but it also can cause genital symptoms. HSV-2 most often causes painful genital lesions, but also can affect the mouth. HSV, like other genital ulcer diseases, increases the risk of acquiring or transmitting HIV by providing a point of entry for the virus. Pregnant women who develop a primary episode of genital herpes can pass the virus to their fetus, which may cause spontaneous abortion, premature delivery or potentially fatal neonatal infection. HSV remains in certain nerve cells throughout a person's life, causing periodic symptoms and/or viral shedding. Many persons infected with HSV never notice symptoms, but can still transmit the virus to others because of this intermittent viral shedding. This life-long ability to unknowingly transmit the virus is one of the reasons that HSV is so prevalent among sexually active adults.

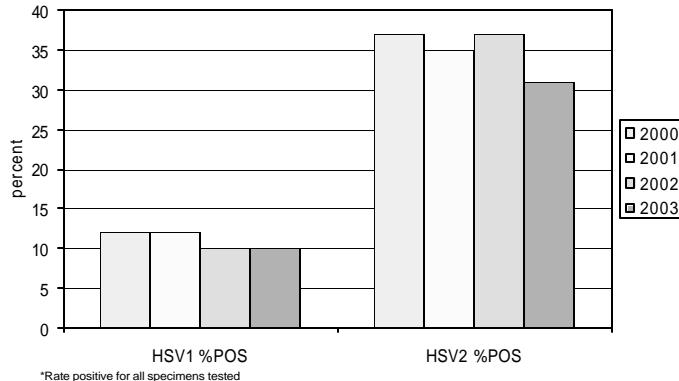

The IDPH Division of Laboratories began performing herpes viral tissue culture testing on specimens submitted by Illinois STD clinics in December 1999.

Figure 27. Herpes Testing at IDPH Laboratories, 2000-2003

Between 2000 and 2003, the number of specimens collected from genital sites submitted annually for herpes testing increased 142 percent (435 to 1,051) (Figure 27).

Figure 28. Herpes Positivity Rates* at IDPH Laboratories, 2000-2003

Of the 436 specimens (41%) that were positive in 2003, 110 (25%) were identified as HSV-1 and 326 (75%) were identified as HSV-2 (Figure 28).

2003

2003 Hepatitis Summary

Hepatitis is a viral infection that causes inflammation of the liver. There are several types of the virus, including hepatitis A, B and C. Some hepatitis viruses (B and C) can spread by sexual contact and injection drug use. Hepatitis A (HAV) is typically spread by the fecal-oral route. Infection with the hepatitis B virus (HBV) can be mild or severe, or may cause no symptoms. HBV is spread by direct contact with blood or body fluids of infected people, most commonly by sharing drug needles; through sexual contact; or from an infected mother to her infant during childbirth. Among adults, 90 percent to 94 percent of persons infected with HBV recover completely and have no long-term effects. However, 6 percent to 10 percent become chronic carriers of the virus and are at risk of developing cirrhosis or liver cancer. In Illinois, there were 130 reported cases of HBV, 186 HAV and 22 acute HCV in 2003.

The IDPH STD and Immunization Programs support the integration of hepatitis prevention services into STD clinics and selected other sites serving clients considered to be at increased risk of hepatitis infection, such as MSM and IDUs (injection drug users). These services include providing adult hepatitis A and B vaccine for eligible clients (age 18 and older and not previously vaccinated) and hepatitis C testing for IDUs. In 2003, using grant funds from the U.S. Centers for Disease Control and Prevention (CDC), these clinics provided hepatitis A and B vaccination to 6,109 clients (31% of those eligible) and tested 440 IDUs for hepatitis C.

Figure 29.

Of the clients who started the 3-dose vaccine series for hepatitis A and/or B, over 40 percent returned for the second dose and over 20 percent returned for the third dose (Figure 29).

Hepatitis A and B Vaccination* Series Completion Rates at 30 STD/Hepatitis Integration Sites in Illinois Excluding Chicago, 2003			
	No. Beginning Series	Dose 2	Dose 3
Hepatitis A	4,774	2,109 (44%)	1,050 (22%)
Hepatitis B	6,284	2,707 (43%)	1,243 (20%)

*includes monovalent and bivalent vaccine products

Figure 30a.

The overall vaccine acceptance rate was higher for identified high-risk clients (Figure 30a). Of the 440 IDUs tested for hepatitis C in 2003, the positivity rate was 33 percent (Figure 30b).

Hepatitis Vaccination Rates* at 30 STD Integration Sites in Illinois Excluding Chicago, by Risk Population, 2003			
	MSM n=[Hep A, 910], [Hep B, 733]	IDUs n=[Hep A, 941], [Hep B, 834]	Total Clients n=19,447

2003 Syphilis Behavioral Risk Assessment Outcomes

Public health departments contact persons who are infected and reported with early syphilis to provide disease intervention services including partner notification and risk reduction counseling. Risk assessment data from these interviews are collected and tabulated to help analyze and describe common risk behaviors of infected clients and develop targeted interventions. Both the Chicago and IDPH STD programs collect data on sexual orientation and HIV status.

Since 2000, the percentage of cases occurring in MSM has increased significantly, from 13 percent of reported primary and secondary cases (52 of 412) in 2000 to 55 percent (206 of 374) in 2003. During this same time period, the percentage of cases among females decreased from 44 percent (181 of 412) to only 13 percent (48 of 374) (Figure 31).

Figure 31.

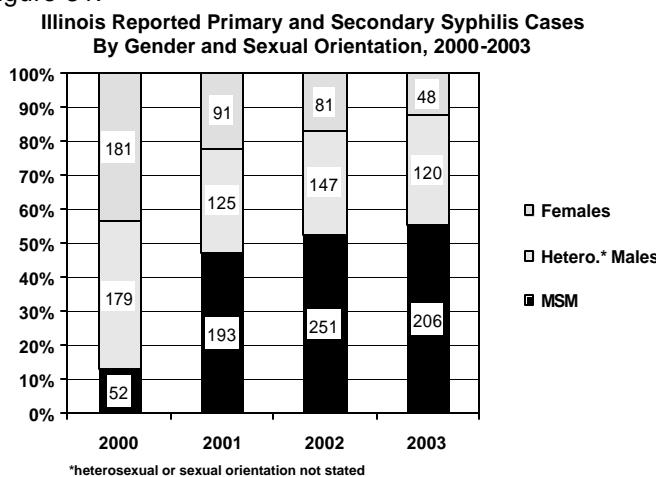

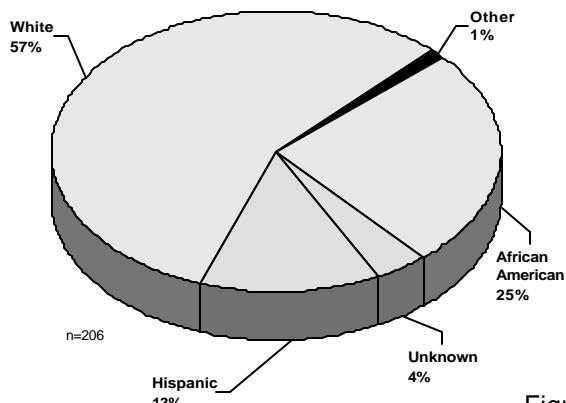

Figure 32.

Illinois Reported Primary and Secondary Syphilis Cases Among MSM By Race*/Ethnicity, 2003

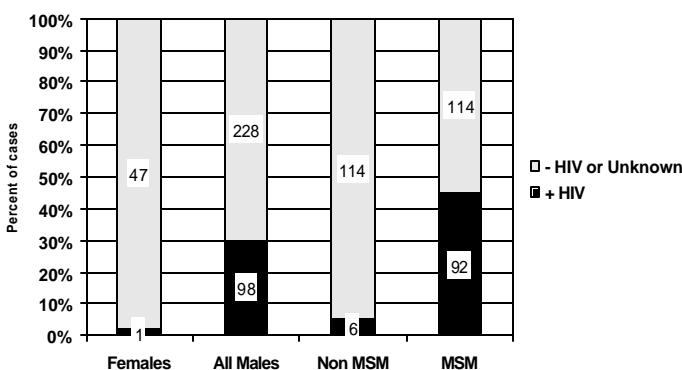

In 2003, of the 326 males reported with primary or secondary syphilis, 206 (63%) were MSM. The majority (57%) of MSM were white (Figure 32).

Coinfection rates for HIV and syphilis in Illinois were higher among MSM than among heterosexual clients. In 2003, of the 206 MSM reported with primary or secondary syphilis, 92 (45%) were coinfected with HIV (Figure 33).

Figure 33.

Illinois Reported Primary and Secondary Syphilis Cases HIV Status By Gender and Sexual Orientation, 2003

2003

In Illinois excluding Chicago, IDPH collects information in addition to sexual orientation and HIV status for counseled clients. These additional risk assessment data describe behavioral risks of counseled clients during the 12 months prior to being diagnosed with early syphilis. These data can be stratified by demographic variables as well as sexual orientation.

In 2003, syphilis behavioral risk assessment forms were submitted to IDPH from local health departments for 66 males and 15 females diagnosed with and counseled for primary or secondary syphilis. Of the 66 males, 36 (55%) were MSM.

Of the 81 clients completing a behavioral risk assessment form, 30 percent (24) indicated illegal drug use (marijuana, cocaine, crack, heroin, methamphetamine, Ecstasy, or GHB (gamma hydroxybutyrate)), often taken in combination with an erectile dysfunction drug such as Viagra. Reported drug use was less common among MSM (19%) than other clients (Figure 34), but MSM reported a wider variety of drugs used, including all of the drugs listed here. Females reported only marijuana and cocaine use. Other differences noted between MSM and heterosexual clients were that heterosexual clients were more likely to have been incarcerated, traded sex for drugs or money and have sex with a sex worker; MSM were more likely to have traveled out of their county of residence to meet sexual partners, have anonymous sex, meet partners through the internet or at a bath house or adult book store and have six or more sexual partners. At least 30 percent of all clients reported not using condoms (Figure 34).

Figure 34.

Syphilis Behavioral Risk Assessment Responses for Clients Counseled for Primary and Secondary Syphilis			
Risk Behaviors Reported During the Past 12 Months By Gender and Sexual Orientation			
Illinois Excluding Chicago, 2003			
	Females n=15	Males (non- MSM) n=30	MSM* n=36
History of an STD	33%	43%	42%
Incarcerated	20%	23%	0%
Sex for drugs/money	20%	30%	14%
Sex with sex worker	0%	33%	8%
Sex outside of residence county	27%	33%	69%
Six or more sex partners	7%	3%	20%
Anonymous sex	7%	27%	61%
Never use condoms	40%	30%	31%
Oral sex only	0%	7%	14%
Met partners through internet	0%	0%	14%
Met partners at bath house or adult book store	0%	0%	25%
Drug use	40%	37%	19%

* Men who have sex with men

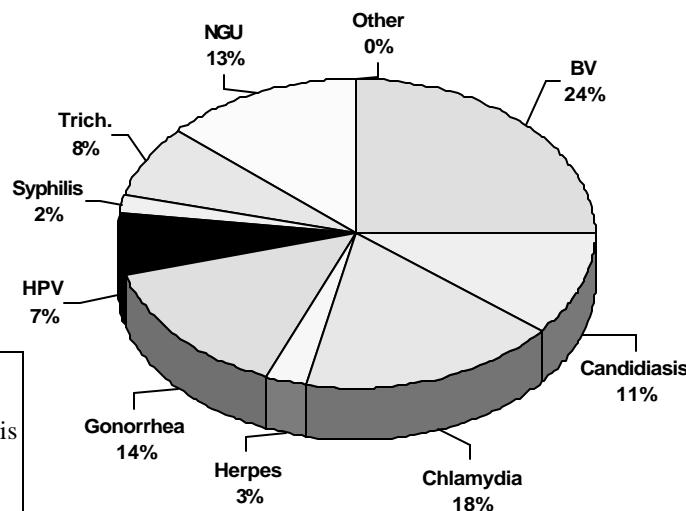

It is important to note that 14 percent of MSM reported oral sex as their only sexual contact within the prior 12 months. Oral sex is perceived by many clients as a safer sexual activity when trying to avoid infection with HIV, but since syphilis lesions can occur on the mouth, syphilis can easily be transmitted through oral sex.

2003 STD Clinic Demographic and Behavioral Data (Illinois Excluding Chicago)

In 2003, the IDPH STD Section collected demographic and behavioral data from 37 STD clinics in Illinois excluding Chicago. Staff at these clinics submit to IDPH a behavioral risk assessment survey (RAS) for each client clinic visit and the forms are scanned into a database. IDPH is then able to tabulate both statewide and individual clinic data, including the number of STD clinic visits by month, age, race, gender and clinical impression/diagnosis as well as behavioral risk information. Data for non-reportable STDs, such as human papilloma virus (HPV or genital warts) and herpes, are included.

In 2003, STD clinic clients were diagnosed with many conditions in addition to reportable STDs (gonorrhea, chlamydia, syphilis, and chancroid) (Figure 35).

Figure 35.
Illinois Excluding Chicago STD Clinic Diagnoses,* 2003
n=22,263

*Clinical impression at time of exam, where a diagnosis was determined;
Data from STD clinic risk assessment surveys

The majority of visits (51 percent; 17,269 of the 33,710 visits where age and gender were reported) during 2003 to STD clinics outside of Chicago were among clients ages 15 to 24 years. Among all 5-year age groups, clients ages 20 to 24 years accounted for the greatest percentage of visits, 33 percent. However, it is important to note that STD clinics provided services to a significant number of adolescents - 3,639 females (23 percent of female visits) and 2,621 males (15 percent of male visits).

During 2003, whites accounted for 49 percent (16,451) of the 33,516 STD clinic visits where race and gender were reported and African Americans accounted for 44 percent (14,702) of visits. Among males, 50 percent of visits were among whites and, of the female clients, 48 percent were white. Hispanics accounted for 12 percent (4,156) of visits (11 percent of females and 13 percent of males).

The age, race and ethnic distribution of STD clinic clients has been similar in each of the past three years. From 2001 to 2003, the male/female ratio decreased slightly from 1.2 to 1.1 (Figure 38).

Behavioral risk information on the RAS can be linked to the IDPH laboratory STD test result by the laboratory specimen bar code. The tables on the following page provide risk assessment data for 2003 by disease for gonorrhea and chlamydia and by gender (Figures 36 and 37).

2003

Overall, 15 percent of STD clinic clients in 2003 reported never using condoms and 9 percent had at least six sex partners in the past year. Among clients with a positive test for gonorrhea or chlamydia, an even greater percentage (16% and 13%, respectively) reported six or more sex partners (Figure 36).

Clients reporting prior vaccination for hepatitis B have increased from 29 percent of client visits in 2001 (when this service was first offered by IDPH) to 36 percent in 2003, indicating that STD clinic staff are appropriately targeting this service to clients at increased risk (Figures 36 and 37).

Snorting drugs was more common in 2003 among STD clinic clients (17 percent of records) than injecting drugs (4 percent of records) (Figures 36 and 37).

Females had higher hepatitis B vaccination and HIV testing rates than males during 2003 and reported fewer sex partners. Females also reported a slightly higher rate of never using condoms than males (Figure 37).

The STD clinic client data collection system is based on visits and not individual clients; therefore, clients may be counted more than once per year. In 2003, risk assessment data were collected for 34,094 client visits, an 18 percent increase from 28,928 in 2001 when data collection with the current system was implemented. In each year, male visits outnumbered female visits (Figure 38).
